

Check Your Answers on Integer Operations!

There are a number of methods used to teach operations with integers and eventually operations with all real numbers from movement on the number line to memorizing specific rules. A more visual approach has been presented here, using students' understanding that being "in the red" indicates an amount owed and being "in the black" indicates a positive amount available for use, the preferred bottom line in business. Based on these concepts, a black chip or circle will represent +1 and a red chip or circle will represent -1. Manipulatives such as checkers can easily be used to mirror the processes presented.

1. -2

Regroup using the Commutative Property:

$$\underbrace{(-) (-) (-) (-) (-)}_{-5} + \underbrace{(+)(+)(+)}_{+3} = \underbrace{(-)(+)}_{-1+1=0} + \underbrace{(-)(+)}_{-1+1=0} + \underbrace{(-)(+)}_{-1+1=0} + (-) + (-) = -2$$

2. -6

$$\underbrace{(-) (-) (-) (-)}_{-4} + \underbrace{(-) (-)}_{-2} = \underbrace{(-) (-) (-) (-) (-) (-)}_{-6}$$

No need to memorize rules when you can visualize the combination!

3. -5

Subtraction is usually introduced as "taking away" the amount to be subtracted. To model $(-6) - (-1)$, begin with 6 red chips. Subtract (-1) by taking away 1 red chip as shown to the right.

$$\underbrace{(-) (-) (-) (-) (-) (-)}_{-6} \text{ with } 1 \text{ chip crossed out} = -5$$

4. -4

Begin with 3 red chips to model $(-3) - 1$. In this case, 1 black chip would be needed to subtract +1. Add one zero which is a black-and-red pair in order to take away 1 black chip.

$$\underbrace{(-) (-) (-)}_{-3} + \underbrace{(+)(-)}_{1+(-1)=0} = -4 \quad \text{OR} \quad \underbrace{(-) (-) (-)}_{-3} + \underbrace{(-)}_{-1} = -4$$

Do you see why subtraction is often redefined as "adding the opposite"?

$(-3) - 1$ could be written as $(-3) + (-1)$.

Rather than taking away 1 black chip, add 1 red chip.

5. -5

Can you mentally picture those positives and negatives, combining as you regroup, without actually seeing those "chips"?

6. -6

Multiplication is a short-cut for repeated addition. In other words, (-3) times 2 means that (-3) is added 2 times: $(-3) + (-3)$ as shown to the right.

$$\underbrace{(-) (-) (-)}_{-3 \text{ once}} + \underbrace{(-) (-) (-)}_{-3 \text{ twice}} = -6$$

7. 2

If multiplying by a *positive* number indicates the number of times that number is added, then multiplying by a *negative* number would indicate the number of times that number is subtracted. (-2) times (-1) means that (-2) or 2 red chips are taken away (from 0) once.

$$\underbrace{(+)(-)}_{1+(-1)=0} + \underbrace{(+)(-)}_{1+(-1)=0} = +2$$

8. 3

Recall your earliest understanding of division; how many times does -2 "go into" -6 ? Visualize the number of groups of 2 red chips there are in -6 which is obviously 3.

9. -2

Division is the inverse operation of multiplication. If $-8 \div 4$ is equal to some number, then some number multiplied by 4 (or repeated four times) will equal -8 . Can you picture this without using chips?

10. -24

Absolutely correct!!

Perfect score? Yes! You've got this!!
